

## AFINITOR®

(everolimus)

### **NAME OF THE MEDICINE**

The active ingredient of Afinitor is everolimus.

The chemical name is 40-O-(2-hydroxyethyl)-rapamycin or 40-O-(2-hydroxyethyl)-sirolimus. Its molecular formula is C<sub>53</sub>H<sub>83</sub>NO<sub>14</sub> and its molecular weight is 958.2.

The structural formula of everolimus is:

### **DESCRIPTION**

Everolimus is a white to faintly yellow powder practically insoluble in water but soluble in organic solvents such as ethanol and methanol.

CAS number: 159351-69-6

Excipients: (Tablets) Butylated hydroxytoluene, magnesium stearate, lactose monohydrate, hypromellose, crospovidone, lactose anhydrous.

## **PHARMACOLOGY**

### **Pharmacodynamics**

#### **Mechanism of Action**

Everolimus is a signal transduction inhibitor targeting mTOR (mammalian target of rapamycin), or more specifically, mTORC1 (mammalian 'target of rapamycin' complex 1). mTOR is a key serine-threonine kinase playing a central role in the regulation of cell growth, proliferation and survival. The regulation of mTORC1 signalling is complex, being modulated by mitogens, growth factors, energy and nutrient availability. mTORC1 is an essential regulator of global protein synthesis downstream on the PI3K/AKT pathway, which is dysregulated in the majority of human cancers.

Two primary regulators of mTORC1 signaling are the oncogene suppressors tuberous-sclerosis complexes 1 & 2 (TSC1, TSC2). Loss or inactivation of either TSC1 or TSC2 leads to elevated rheb-GTP levels, a ras family GTPase, which interacts with the mTORC1 complex to cause its activation. mTORC1 activation leads to a downstream kinase signaling cascade, including activation of the S6K1. In tuberous sclerosis syndrome, a genetic disorder, inactivating mutations in either the TSC1 or the TSC2 gene lead to hamartoma formation throughout the body.

#### **Pharmacodynamic properties**

Everolimus exerts its activity through high affinity interaction with the intracellular receptor protein FKBP12. The FKBP12/everolimus complex binds to mTORC1, inhibiting its signalling capacity. mTORC1 signalling is effected through modulation of the phosphorylation of downstream effectors, the best characterised of which are the translational regulators S6 ribosomal protein kinase (S6K1) and eukaryotic elongation factor 4E-binding protein (4E-BP). Disruption of S6K1 and 4E-BP1 function, as a consequence of mTORC1 inhibition, interferes with the translation of mRNAs encoding pivotal proteins involved in cell cycle regulation, glycolysis and adaptation to low oxygen conditions (hypoxia). This inhibits tumour growth and expression of hypoxia-inducible factors (e.g. HIF-1 transcription factors); the latter resulting in reduced expression of factors involved in the potentiation of tumour angiogenic processes (e.g. the vascular endothelial growth factor VEGF). Everolimus is an inhibitor of the growth and proliferation of tumour cells, endothelial cells, fibroblasts and blood vessel-associated smooth muscle cells.

In a mouse neuronal model of TS in which TSC1 is ablated in most neurons during cortical development, everolimus was shown to markedly improve survival and neurological following repeated intraperitoneal administration.

## **Pharmacokinetics**

### **Absorption**

In patients with advanced solid tumours, peak everolimus concentrations are reached 1 to 2 hours after administration of an oral dose of 5 to 70 mg everolimus under fasting conditions or with a light fat-free snack.  $C_{max}$  is dose-proportional between 5 and 10 mg. AUC shows dose-proportionality over the 5 to 70 mg dose range.

### **Effects of Food**

In healthy subjects, high fat meals reduced systemic exposure to Afinitor 10 mg (as measured by AUC) by 22% and the peak plasma concentration  $C_{max}$  by 54%. Light fat meals reduced AUC by 32% and  $C_{max}$  by 42%. Food, however, had no apparent effect on the post absorption phase concentration-time profile.

### **Distribution**

The blood-to-plasma ratio of everolimus, which is concentration-dependent over the range of 5 to 5,000 ng/mL, is 17% to 73%. The amount of everolimus confined to the plasma is approximately 20% at blood concentrations observed in cancer patients given 10 mg/day of Afinitor. Plasma protein binding is approximately 74% both in healthy subjects and patients with moderate hepatic impairment.

Following intravenous administration in a rat model, everolimus was shown to cross the blood-brain barrier in a non-linear dose-dependent manner, suggesting saturation of an efflux pump at the blood-brain barrier. Brain penetration of everolimus has also been demonstrated in rats receiving oral doses of everolimus.

### **Metabolism**

Everolimus is a substrate of CYP3A4 and P-glycoprotein (PgP). Following oral administration, it is the main circulating component in human blood. Six main metabolites of everolimus have been detected in human blood, including three monohydroxylated metabolites, two hydrolytic ring-opened products, and a phosphatidylcholine conjugate of everolimus. These metabolites were also identified in animal species used in toxicity studies, and showed approximately 100-times less activity than everolimus itself. Hence, the parent substance is considered to contribute the majority of the overall pharmacological activity of everolimus.

## **Excretion**

No specific excretion studies have been undertaken in cancer patients; however, data are available from the transplant setting. Following the administration of a single dose of radiolabeled everolimus in conjunction with cyclosporin, 80% of the radioactivity was recovered from the faeces, while 5% was excreted in the urine. The parent substance was not detected in the urine or faeces.

## **Steady-state pharmacokinetics**

After daily administration of everolimus in patients with advanced solid tumours, steady-state  $AUC_{0-\tau}$  was dose-proportional over the range of 5 to 10 mg. Steady-state was achieved within two weeks.  $C_{max}$  is dose-proportional between 5 and 10 mg. There was a significant correlation between  $AUC_{0-\tau}$  and pre-dose trough concentration at steady-state on the daily regimen. Mean elimination half-life is approximately 30 hours.

## **Hepatic impairment**

The average AUC of everolimus in 8 subjects with moderate hepatic impairment (Child-Pugh Class B) was twice that found in 8 subjects with normal hepatic function. AUC was positively correlated with serum bilirubin concentration and with prolongation of prothrombin time and negatively correlated with serum albumin concentration. The impact of severe hepatic impairment (Child-Pugh Class C) has not been assessed (see Dosage and Administration and Precautions).

## **Renal impairment**

In a population pharmacokinetic analysis of 170 patients with advanced cancer, no significant influence of creatinine clearance (25 to 178 mL/min) was detected on CL/F of everolimus. Post-transplant renal impairment (creatinine clearance range 11 to 107 mL/min) did not affect the pharmacokinetics of everolimus in transplant patients.

## **Paediatrics**

There is no relevant indication for use of Afinitor in the paediatric cancer population (see Dosage and Administration). In patients with SEGA, intra-patient steady-state trough concentrations were dose-proportional at daily doses of 1.5 to 14.6 mg/m<sup>2</sup> (see Dosage and Administration).

## **Elderly**

In a population pharmacokinetic evaluation in cancer patients, no significant influence of age (27 – 85 years) on oral clearance (CL/F: range 4.8 to 54.5 litres/hour) of everolimus was detected.

## **Ethnicity**

Asian patients with neuroendocrine tumours (NETs) showed a consistent pattern of reduced clearance, and higher AUC values, with higher C<sub>min</sub> values compared to non-Asian patients (see Precautions).

Based on analysis of population pharmacokinetics, oral clearance (CL/F) is, on average, 20% higher in black transplant patients.

## **Exposure-response relationships**

There was a moderate correlation between the decrease in the phosphorylation of 4E-BP1 (P4E-BP1) in tumour tissue and the average everolimus C<sub>min</sub> at steady state in blood after daily administration of 5 or 10 mg everolimus. Further data suggest that the inhibition of phosphorylation of the S6 kinase is very sensitive to the mTOR inhibition by everolimus. Inhibition of phosphorylation of eIF-4G was complete at all C<sub>min</sub> values after the 10 mg daily dose.

In patients with SEGA, higher everolimus trough concentrations appear to be associated with larger reductions in SEGA volume. However, as responses have been observed at trough concentrations as low as 2 ng/mL, once acceptable efficacy has been achieved, additional dose increase may not be necessary (see Dosage and Administration).

## **CLINICAL TRIALS**

### **Advanced neuroendocrine tumours of pancreatic origin**

RADIANT-3 (Study CRAD001C2324), a randomised, double-blind, multicentre phase III study of Afinitor plus best supportive care (BSC) versus placebo plus BSC in patients with progressive, unresectable or metastatic, well or moderately differentiated pancreatic neuroendocrine tumours (pNET), demonstrated a statistically significant clinical benefit of Afinitor over placebo by a 2.4-fold prolongation in median progression-free-survival PFS (11.04 months versus 4.6 months), resulting in a 65% risk reduction in PFS (HR 0.35; 95%CI: 0.27, 0.45; one sided p<0.0001) (see Table 1 and Figure 1).

RADIANT-3 enrolled patients with advanced pNET whose disease had progressed within the prior 12 months, was well or moderately differentiated, and unresectable or metastatic. Patients were stratified by prior cytotoxic chemotherapy (yes/no) and by WHO performance status (0 vs. 1 and 2). Treatment with somatostatin analogs was allowed as part of BSC.

The primary endpoint for the trial was PFS evaluated by RECIST (Response Evaluation Criteria in Solid Tumours, version 1.0) as per investigator radiological review. After documented radiological progression, patients could be unblinded by the investigator: those randomised to placebo were then able to receive open-label Afinitor.

**Attachment 1: Product information for AusPAR Afinitor everolimus Novartis Pharmaceuticals Australia Pty Ltd PM-2011-01215-3-4 Final 26 February 2013. This Product Information was approved at the time this AusPAR was published.**

Secondary endpoints include safety, objective response rate ORR (complete response (CR) or partial response (PR)), response duration, and overall survival OS.

In total, 410 patients were randomised 1:1 to receive either Afinitor 10mg/day (n=207) or placebo (n=203). Demographics were well balanced (median age 58 years, 55.4% male, 78.5% Caucasian).

**Table 1 RADIANT-3 – Progression Free Survival results**

Analysis	N	Afinitor N=207	Placebo N=203	Hazard Ratio (95%CI)	p-value <sup>b</sup>
	410	Median progression-free survival (months) (95% CI)			
Investigator		11.04	4.60	0.35	<0.0001
radiological review		(8.41 to 13.86)	(3.06 to 5.39)	(0.27 to 0.45)	
Independent		11.40	5.39	0.34	<0.0001
radiological review <sup>a</sup>		(10.84 to 14.75)	(4.34 to 5.55)	(0.26 to 0.44)	

<sup>a</sup> Includes adjudication for discrepant assessments between investigator radiological review and central radiological review

<sup>b</sup>One-sided p-value from a stratified log-rank test

**Figure 1 RADIANT-3 – Kaplan-Meier progression-free survival curves (investigator radiological review)**

Eighteen-months PFS rates were 34.2% for Afinitor therapy compared to 8.9% for placebo. The overall survival results are not yet mature and no statistically significant difference in OS was noted (HR=0.99 (95% CI 0.68 to 1.43) in an updated analysis). Crossover of >74% of patients from placebo to open-label Afinitor following disease progression likely confounded the detection of any treatment-related difference in OS.

#### **Advanced neuroendocrine tumours of non-pancreatic origin**

RADIANT-2 (Study CRAD001C2325), a randomised, double-blind, multicentre phase III study of Afinitor plus depot octreotide (Sandostatin LAR<sup>®</sup>) versus placebo plus depot octreotide in patients with advanced neuroendocrine tumours (carcinoid tumour) primarily of gastrointestinal or lung origin showed evidence of borderline clinical efficacy of Afinitor over placebo by a 5.1-month prolongation in median PFS (16.43 months versus 11.33 months; HR 0.77; 95%CI: 0.59 to 1.00; one sided p=0.026), resulting in a 23% risk reduction in primary PFS (see Table 2 and Figure 2). The efficacy data shown are insufficient in the context of the product's safety profile and lack of evidence of overall survival benefit in RADIANT-2 to support approval in patients with non-pancreatic advanced neuroendocrine tumours.

RADIANT-2 enrolled patients with advanced neuroendocrine tumours (carcinoid tumour) primarily of gastrointestinal or lung origin whose disease had progressed within the prior 12 months and had a history of secretory symptoms. 80.1% of the patients in the Afinitor

group received somatostatin analog therapy prior to study entry compared to 77.9% in the placebo group.

The primary endpoint is PFS evaluated by RECIST (version 1.0) as per Independent radiological review. After documented radiological progression, patients could be unblinded by the investigator: those randomised to placebo were then able to receive open-label Afinitor.

Secondary endpoints include safety, objective response, response duration, and overall survival.

In total, 429 patients were randomised 1:1 to receive either Afinitor 10mg/day (n=216) or placebo (n=213), in addition to depot octreotide (Sandostatin LAR®, administered intramuscularly) 30 mg every 28 days. Notable imbalances were evident for several important baseline prognostic factors, mainly in favour of the placebo group.

**Table 2 RADIANT-2 – Progression Free Survival results**

Analysis	N	Afinitor <sup>a</sup> N=216	Placebo <sup>a</sup> N=213	Hazard Ratio (95%CI)	p-value <sup>c</sup>
	429	Median progression-free survival (months) (95% CI)			
Independent radiological review <sup>b</sup>		16.43 (13.67 to 21.19)	11.33 (8.44 to 14.59)	0.77 (0.59 to 1.00)	0.026
Investigator radiological review		11.99 (10.61 to 16.13)	8.61 (8.08 to 11.14)	0.78 (0.62 to 0.98)	0.018

<sup>a</sup> Plus depot octreotide (Sandostatin LAR®)

<sup>b</sup>Includes adjudication for discrepant assessments between investigator radiological review and central radiological review

<sup>c</sup>One-sided p-value from stratified log-rank test

**Figure 2 RADIANT-2 – Kaplan-Meier progression-free survival curves (independent radiologic review)**

Eighteen-months PFS rates were 47.2% for Afinitor therapy plus depot octreotide (Sandostatin LAR<sup>®</sup>) compared with 37.4% for placebo plus depot octreotide (Sandostatin LAR<sup>®</sup>).

The overall survival results are not yet mature and no statistically significant difference in OS was noted (HR for pre-specified adjusted analysis =1.05 (95% CI 0.79 to 1.39) in an updated analysis). Crossover of >58% of patients from placebo to open-label Afinitor following disease progression likely confounded the detection of any treatment-related difference in OS.

### Advanced renal cell carcinoma

RECORD-1 (CRAD001C2240), a phase III, international, multicentre, randomised, double-blind study comparing Afinitor 10 mg/day and placebo, both in conjunction with best supportive care, was conducted in patients with metastatic renal cell carcinoma whose disease had progressed despite prior treatment with VEGFR-TKI (vascular endothelial growth factor receptor tyrosine kinase inhibitor) therapy (sunitinib, sorafenib, or both sunitinib and sorafenib). Prior therapy with bevacizumab, cytokines and chemotherapy was also permitted. Patients were stratified according to Memorial Sloan-Kettering Cancer Center (MSKCC) prognostic score (favourable- vs intermediate- vs. poor-risk groups) and prior anticancer therapy (1 vs. 2 prior VEGFR-TKIs).

Progression-free survival, documented using RECIST (Response Evaluation Criteria in Solid Tumours) and assessed via a blinded, independent central review, was the primary endpoint. Secondary endpoints included safety, objective tumour response rate, overall survival, disease-related symptoms, and quality of life. After documented radiological progression, patients could be unblinded by the investigator: those randomised to placebo were then able to receive open-label Afinitor 10 mg/day. The Independent Data Monitoring Committee recommended termination of this trial at the time of the second interim analysis as the primary endpoint had been met.

In total, 416 patients were randomised 2:1 to receive Afinitor (n=277) or placebo (n=139). Demographics were well balanced (pooled median age 61 years [range 27 to 85], 77% male, 88% Caucasian, 74% one prior VEGFR-TKI therapy).

Results from a planned interim analysis showed that Afinitor was superior to placebo for the primary endpoint of progression-free survival, with a statistically significant 67% reduction in the risk of progression or death (see Table 3 and Figure 3).

**Table 3** **RECORD-1 - Progression Free Survival results**

Population	N	Afinitor N=277	Placebo N=139	Hazard Ratio (95%CI)	p-value
<b>Median progression-free survival (months) (95% CI)</b>					
<b>Primary analysis</b>					
All (blinded independent central review)	416	4.9 (4.0 to 5.5)	1.9 (1.8 to 1.9)	0.33 (0.25 to 0.43)	<0.001 <sup>a</sup>
<b>Supportive/sensitivity analyses</b>					
All (local review by investigator)	416	5.5 (4.6 to 5.8)	1.9 (1.8 to 2.2)	0.32 (0.25 to 0.41)	<0.001 <sup>a</sup>
MSKCC prognostic score					
Favourable risk	120	5.8 (4.0 to 7.4)	1.9 (1.9 to 2.8)	0.31 (0.19 to 0.50)	<0.001 <sup>b</sup>
Intermediate risk	235	4.5 (3.8 to 5.5)	1.8 (1.8 to 1.9)	0.32 (0.22 to 0.44)	<0.001 <sup>b</sup>
Poor risk	61	3.6 (1.9 to 4.6)	1.8 (1.8 to 3.6)	0.44 (0.22 to 0.85)	0.007 <sup>b</sup>
Prior VEGFR-TKI therapy					
Sunitinib only	184	3.9 (3.6 to 5.6)	1.8 (1.8 to 1.9)	0.34 (0.23 to 0.51)	<0.001 <sup>b</sup>
Sorafenib only	124	5.9 (4.9 to 11.4)	2.8 (1.9 to 3.6)	0.25 (0.16 to 0.42)	<0.001 <sup>b</sup>
Sunitinib and sorafenib	108	4.0 (3.6 to 5.4)	1.8 (1.8 to 2.0)	0.32 (0.19 to 0.54)	<0.001 <sup>b</sup>

<sup>a</sup> Log-rank test stratified by prognostic score

<sup>b</sup> Unstratified one-sided log-rank test

**Figure 3 RECORD-1 - Kaplan-Meier progression-free survival curves**

Six-month PFS rates were 36% for Afinitor therapy compared with 9% for placebo. Confirmed objective tumour responses were observed in 5 patients (2%) receiving Afinitor while none were observed in patients receiving placebo. The progression-free survival advantage therefore primarily reflects the population with disease stabilisation (corresponding to 67% of the Afinitor treatment group).

No statistically significant treatment-related difference in overall survival was noted, although there was a trend in favour of Afinitor (HR 0.82; 95% CI: 0.57 to 1.17; p=0.137). Crossover to open-label Afinitor following disease progression for patients allocated to placebo confounded the detection of any treatment-related difference in overall survival. Subgroup analyses by age (<65 years and ≥65 years) indicated that the Afinitor treatment effect was consistent.

No difference in health-related quality of life was observed in patients receiving Afinitor compared to placebo patients.

### **Subependymal giant cell astrocytoma (SEGA)**

The effectiveness of Afinitor is based on an analysis of change in SEGA volume. Clinical benefit such as improvement in disease-related symptoms or increase in overall survival has not been demonstrated.

An open-label, single-arm trial was conducted to evaluate the safety and efficacy of Afinitor in patients with SEGA associated with TS. Serial radiological evidence of SEGA growth was required for entry. Change in SEGA volume at the end of the core 6-month treatment phase was assessed via an independent central radiology review. In total, 28 patients received treatment with Afinitor; median age was 11 years (range 3-34), 61% male, 86% Caucasian. Four patients had surgical resection of their SEGA lesions with subsequent re-growth prior to receiving Afinitor treatment. After the core treatment phase, patients could continue to receive Afinitor treatment as part of an extension treatment phase where SEGA volume was assessed every 6 months. The median duration of treatment was 24.4 months (range 4.7-37.3 months).

At 6 months, 9 out of 28 patients (32%, 95% CI: 16% to 52%) had a  $\geq 50\%$  reduction in the tumor volume of their largest SEGA lesion. Duration of response for these 9 patients ranged from 97 to 946 days with a median of 266 days. Seven of these 9 patients had an ongoing volumetric reduction of  $\geq 50\%$  at the data cutoff.

Three of 4 patients who had prior surgery experienced a  $\geq 50\%$  reduction in the tumor volume of their largest SEGA lesion. One of these three patients responded by month 6. No patient developed new lesions.

## **INDICATIONS**

For the treatment of patients with:

- Progressive, unresectable or metastatic, well or moderately differentiated neuroendocrine tumours (NETs) of pancreatic origin.
- Advanced renal cell carcinoma after failure of treatment with sorafenib or sunitinib.
- Subependymal giant cell astrocytoma (SEGA) associated with tuberous sclerosis (TS) who require therapeutic intervention but are not candidates for curative surgical resection.

## **CONTRAINDICATIONS**

Hypersensitivity to the active substance, to other rapamycin derivatives or to any of the excipients (see Precautions).

## **PRECAUTIONS**

### **Non-infectious pneumonitis**

Non-infectious pneumonitis is a class effect of rapamycin derivatives. Cases of non-infectious pneumonitis (including interstitial lung disease) have also been described in patients taking Afinitor (see Adverse Effects). Some of these have been severe and on rare occasions, a fatal

outcome was observed. A diagnosis of non-infectious pneumonitis should be considered in patients presenting with non-specific respiratory signs and symptoms such as hypoxia, pleural effusion, cough or dyspnoea, and in whom infectious, neoplastic and other non-medicinal causes have been excluded by means of appropriate investigations. Patients should be advised to report promptly any new or worsening respiratory symptoms.

Patients who develop radiological changes suggestive of non-infectious pneumonitis and have few or no symptoms may continue Afinitor therapy without dose alteration. If symptoms are moderate, consideration should be given to interruption of therapy until symptoms improve. The use of corticosteroids may be indicated:

- In patients with advanced neuroendocrine tumours of pancreatic origin or advanced renal cell carcinoma, Afinitor may be reintroduced at 5 mg daily.
- In patients with SEGA, Afinitor may be reintroduced at a daily dose approximately 50% lower than the dose previously administered.

For cases where symptoms of non-infectious pneumonitis are severe, Afinitor therapy should be discontinued and the use of corticosteroids may be indicated until clinical symptoms resolve.

- In patients with advanced neuroendocrine tumours of pancreatic origin or advanced renal cell carcinoma, therapy with Afinitor may be re-initiated at a reduced dose of 5 mg daily depending on the individual clinical circumstances.
- In patients with SEGA, therapy with Afinitor may be re-initiated at a daily dose approximately 50% lower than the dose previously administered depending on the individual clinical circumstances.

### **Infections**

Afinitor has immunosuppressive properties and may predispose patients to bacterial, fungal, viral or protozoan infections, including infections with opportunistic pathogens (see Adverse Effects). Localised and systemic infections, including pneumonia, other bacterial infections, invasive fungal infections, such as aspergillosis or candidiasis and viral infections including reactivation of hepatitis B virus, have been described in patients taking Afinitor. Some of these infections have been severe (e.g. leading to respiratory or hepatic failure) and occasionally have had a fatal outcome. Physicians and patients should be aware of the increased risk of infection with Afinitor. Treat pre-existing invasive fungal infections prior to starting treatment with Afinitor. While taking Afinitor, be vigilant for symptoms and signs of infection; if a diagnosis of infection is made, institute appropriate treatment promptly and consider interruption or discontinuation of Afinitor.

If a diagnosis of invasive systemic fungal infection is made, Afinitor should be promptly and permanently discontinued and the patient treated with appropriate antifungal therapy.

### **Impaired Wound Healing**

Impaired wound healing is a class effect of rapamycin derivatives, including Afinitor. Caution should therefore be exercised with the use of Afinitor in the peri-surgical period.

### **Hypersensitivity**

Hypersensitivity reactions manifested by symptoms including, but not limited to, anaphylaxis, dyspnoea, flushing, chest pain or angioedema (eg swelling of the airways or tongue, with or without respiratory impairment) have been observed with everolimus (see Contraindications).

### **Oral ulceration**

Mouth ulcers, stomatitis and oral mucositis have been seen in patients treated with Afinitor (see Adverse Effects). In such cases topical treatments are recommended, but alcohol- or peroxide-containing mouthwashes should be avoided as they may exacerbate the condition. Antifungal agents should not be used unless fungal infection has been diagnosed (see Interactions with Other Medicines).

### **Ethnicity**

In Asian patients, with NETs, the reported adverse events of hypertension were 1.95 fold higher (17.6% vs. 9.0%), of pneumonitis 1.88 fold higher (13.2% vs. 7.0%), and of hyperglycaemia 1.59 fold higher (29.4% vs. 18.4%) than in Caucasian patients.

### **Renal failure events**

Cases of renal failure (including acute renal failure), some with a fatal outcome, have been observed in patients treated with Afinitor (see ADVERSE EFFECTS section, see also Laboratory tests and monitoring).

### **Hepatic impairment**

Exposure to everolimus was increased in patients with mild (Child-Pugh A), moderate (Child-Pugh B), and severe (Child-Pugh C) hepatic impairment (see Dosage and Administration and Precautions).

Everolimus is not recommended for use in patients with severe hepatic impairment (Child-Pugh C) (see Dosage and Administration and Pharmacokinetics).

### **Effects on fertility**

Everolimus completely impaired male rat fertility at an everolimus dose that resulted in a drug exposure (blood AUC) that was slightly below 1 the expected maximum human value, and sperm number and motility were reduced. Testicular atrophy was observed in all animal species tested (mouse, rat, minipigs and monkey) at drug exposures similar to the expected clinical exposure (blood AUC). There was evidence for partial recovery of fertility over a period approximately equivalent to the treatment period. Female rat fertility could not be assessed at dose resulting in an adequate drug exposure (blood AUC).

### **Use in Pregnancy (Category C)**

There are no adequate data from the use of everolimus in pregnant women and the potential risk to the foetus is unknown. In a rat study in which oral treatment started before mating and continued to the end of the period of organogenesis, treatment resulted in increased pre- and post-implantation losses. There was a low incidence of foetal cleft sternum, the significance of which is uncertain because it occurred at a dose giving a high foetal resorption rate. Systemic drug exposures (blood AUC) with the doses used in this study were below the expected human value at 10 mg/day. Treatment of pregnant rabbits during the period of organogenesis slightly increased late fetal resorptions but did not otherwise affect foetal development. The highest dose used in this study gave a systemic drug exposure (blood AUC) that was below the expected human value<sup>2</sup> at 10 mg/day. Women of childbearing potential should be advised to use highly effective contraception methods while they are receiving Afinitor and up to 8 weeks after treatment has been stopped.

### **Use in Lactation**

It is not known whether everolimus is excreted in human milk. In animal studies, everolimus and/or its metabolites readily passed into the milk of lactating rats. Women taking Afinitor should not breast-feed.

### **Paediatric Use**

PNETs and RCC: Afinitor is not recommended for use in paediatric cancer patients.

SEGA: Afinitor has not been studied in paediatric SEGA patients < 3 years of age and is currently not recommended for use in this age group (see Dosage and Administration).

<sup>1</sup> At high dose (5 mg/kg/day), AUC0-24 hr=414.8 ng.hr/mL vs human AUC=514 at 10 mg/day.

<sup>2</sup> AUC=225.6 ng.hr/mL at high dose. Vs human AUC of 514 ng.hr/mL at 10 mg/day.

### **Use in Elderly**

In patients over 65 years, with NETs, the reported incidences of dehydration, hypomagnesaemia and pneumonitis was more than 1.4 fold higher than for patients 65 years or younger.

### **Genotoxicity**

Everolimus did not show genotoxicity in in vitro tests for gene mutation (bacteria and mammalian cells), and in an in vitro test and an in vivo mouse micronucleus assay for clastogenic activity.

### **Carcinogenicity**

Long-term carcinogenicity studies have been carried out in mice and rats and no oncogenic responses were observed. Drug exposures (blood AUC) were up to 4-times <sup>3</sup> the expected human value at 10 mg/day in mice, but were less than the expected maximum human value in rats.

### **Effect on laboratory tests**

#### **Renal Function**

Elevations of serum creatinine, usually mild, and proteinuria have been reported in clinical trials (see Adverse Effects). Monitoring of renal function, including measurement of blood urea nitrogen (BUN), urinary protein, or serum creatinine, is recommended prior to the start of Afinitor therapy and periodically thereafter.

#### **Blood glucose and lipids**

Hyperglycaemia, hyperlipidaemia and hypertriglyceridaemia has been reported in clinical trials (see Adverse Effects). Monitoring of fasting serum glucose is recommended prior to the start of Afinitor therapy and periodically thereafter. The appropriate optimal glycaemic control must be achieved before starting a patient on Afinitor.

Octreotide has been associated with a rise in blood glucose which may increase the hyperglycaemic effect of everolimus.

---

<sup>3</sup> AUC<sub>0-24 hr</sub>=2231 ng.hr/mL in mice vs AUC=514 in human at 10 mg/day.

## Haematological parameters

Decreased haemoglobin, lymphocytes, neutrophils and platelets have been reported in clinical trials (see Adverse Effects). Monitoring of complete blood count is recommended prior to the start of Afinitor therapy and periodically thereafter.

## **INTERACTIONS WITH OTHER MEDICINES**

Everolimus is a substrate of CYP3A4, and also a substrate and moderate inhibitor of the multidrug efflux pump P-glycoprotein (PgP). Therefore, absorption and subsequent elimination of everolimus may be influenced by products that affect CYP3A4 and/or PgP. In vitro, everolimus is a competitive inhibitor of CYP3A4 and a mixed inhibitor of CYP2D6.

### **Agents that may increase everolimus blood concentrations**

Everolimus blood concentrations may be increased by substances that inhibit CYP3A4 activity and thus decrease everolimus metabolism.

Everolimus blood concentrations may be increased by inhibitors of PgP that may decrease the efflux of everolimus from intestinal cells.

#### *Moderate CYP3A4 or PgP inhibitors*

Concomitant treatment with moderate inhibitors of CYP3A4 including but not limited to erythromycin, verapamil, cyclosporin, fluconazole, diltiazem, amprenavir, fosamprenavir, aprepitant, or posaconazole) and PgP requires caution. If Afinitor must be co-administered with a moderate CyP3A4 or PgP inhibitor, the patient should be carefully monitored for undesirable effects and the dose reduced if necessary (see Dosage and Administration).

There was an increase in exposure to everolimus in healthy subjects when everolimus was co-administered with:

- erythromycin (a moderate CYP3A4 inhibitor and a PgP inhibitor; Cmax and AUC increased by 2.0- and 4.4-fold, respectively).
- verapamil (a moderate CYP3A4 inhibitor and a PgP inhibitor; Cmax and AUC increased by 2.3-and 3.5-fold, respectively).
- cyclosporin (a CYP3A4 substrate and a PgP inhibitor; Cmax and AUC increased by 1.8- and 2.7-fold, respectively).

Other moderate inhibitors of CYP3A4 and PgP that may increase everolimus blood concentrations include certain antifungal agents (e.g. fluconazole) and calcium channel blockers (e.g. diltiazem).

Grapefruit, grapefruit juice, star fruit, Seville oranges and other foods that are known to affect cytochrome P450 and PgP activity should be avoided during treatment.

***Strong CYP3A4 or PgP inhibitors***

Concurrent treatment with strong inhibitors of CYP3A4 or PgP (including but not limited to ketoconazole, itraconazole, ritonavir and clarithromycin) should be avoided.

There was a significant increase in exposure to everolimus (Cmax and AUC increased by 3.9- and 15.0-fold, respectively) in healthy subjects when everolimus was co-administered with ketoconazole (a strong CYP3A4 inhibitor and PgP inhibitor). An interaction with topically administered ketoconazole cannot be excluded.

**Agents that may decrease everolimus blood concentrations**

Substances that are inducers of CYP3A4 or PgP may decrease everolimus blood concentrations by increasing metabolism or the efflux of everolimus from intestinal cells.

***Strong CYP3A4 inducers***

Concurrent treatment with strong inducers of CYP3A4 or PgP should be avoided (see Interactions with Other Medicines). If Afinitor must be co-administered with a strong CYP3A4 or PgP inducer (eg rifampicin and rifabutin), the patient should be carefully monitored for clinical response. Consider a dose increase of Afinitor when co-administered with strong inducers of CyP3A4 or PgP if alternative treatment is not possible (see Dosage and Administration).

Exercise caution when Afinitor is taken in combination with orally administered CYP3A4 substrates with a narrow therapeutic index due to the potential for drug interactions. If Afinitor is taken with orally administered CYP3A4 substrates with a narrow therapeutic index, the patient should be monitored for undesirable effects described in the product information of the orally administered CYP3A4 substrate.

Pre-treatment of healthy subjects with multiple doses of rifampicin (a CYP3A4 and PgP inducer) 600 mg daily for 8 days followed by a single dose of everolimus, increased everolimus oral-dose clearance nearly 3-fold and decreased Cmax by 58% and AUC by 63%. Other strong inducers of CYP3A4 that may increase the metabolism of everolimus and decrease everolimus blood levels include St. John's wort (*Hypericum perforatum*), corticosteroids (e.g. dexamethasone, prednisone, prednisolone), anticonvulsants (e.g. carbamazepine, phenobarbital, phenytoin,) and anti HIV agents (e.g. efavirenz, nevirapine).

**Agents whose plasma concentration may be altered by everolimus**

Studies in healthy subjects indicate that there are no clinically significant pharmacokinetic interactions between Afinitor and the HMG-CoA reductase inhibitors atorvastatin (a CYP3A4 substrate) and pravastatin (a non-CYP3A4 substrate) and population pharmacokinetic analyses also detected no influence of simvastatin (a CYP3A4 substrate) on the clearance of Afinitor.

In vitro, everolimus competitively inhibited the metabolism of the CYP3A4 substrate cyclosporin and was a mixed inhibitor of the CYP2D6 substrate dextromethorphan. The mean steady-state of everolimus Cmax with an oral dose of 10 mg daily or 70 mg weekly is more than 12- to 36-fold below the Ki-values of the in vitro inhibition. An effect of everolimus on the metabolism of CYP3A4 and CYP2D6 substrates was therefore considered to be unlikely.

## **Vaccinations**

Immunosuppressants may affect the response to vaccination and vaccination during treatment with Afinitor may therefore be less effective. The use of live vaccines should be avoided during treatment with Afinitor. Examples of live vaccines are: intranasal influenza, measles, mumps, rubella, oral polio, BCG, yellow fever, varicella, and TY21a typhoid vaccines.

## **Lactose**

Patients with rare hereditary problems of galactose intolerance, Lapp lactose deficiency or glucose-galactose malabsorption should not take this medicinal product.

## **ADVERSE EFFECTS**

### **Advanced neuroendocrine tumours of pancreatic origin and advanced renal cell carcinoma**

Information about adverse drug reactions (ADRs) is mainly based on data from three randomized, double-blind, placebo-controlled phase III trials:

- RADIANT-3 (CRAD001C2324): Afinitor plus best supportive care in patients with advanced pancreatic neuroendocrine tumours. Median duration of blinded study treatment was 37.8 weeks for patients receiving Afinitor and 16.1 weeks for those receiving placebo.
- RECORD-1 (CRAD001C2240): Afinitor plus best supportive care in patients with advanced renal cell carcinoma. Median duration of blinded study treatment was 141 days for patients receiving Afinitor and 60 days for those receiving placebo.

The most common adverse reactions (incidence  $\geq 10\%$  in at least one phase III trial and suspected to be related to treatment by the investigator) were (in decreasing order): stomatitis, rash, diarrhoea, fatigue, infections asthenia, nausea, peripheral oedema, decreased appetite, headache, pneumonitis, dysgeusia, epistaxis, mucosal inflammation, weight decreased, vomiting, pruritus, cough, dyspnoea, dry skin, nail disorder, and pyrexia. The most common grade 3 - 4 ADRs (incidence  $\geq 2\%$  in at least one phase III trial) were stomatitis, fatigue, diarrhoea, infections, pneumonitis and diabetes mellitus.

Table 4 presents the frequency category of ADRs reported with an incidence of  $\geq 5\%$  for patients receiving Afinitor 10 mg/day in at least one of the phase III pivotal trials; all terms included are based on the highest percentage reported in a pivotal trial. ADRs are listed according to MedDRA system organ class. Within each system organ class, the adverse

reactions are ranked by frequency, with the most frequent reactions first. In addition, the corresponding frequency category using the following convention (CIOMS III) is also provided for each adverse reaction: very common ( $\geq 1/10$ ); common ( $\geq 1/100$  to  $< 1/10$ ); uncommon ( $\geq 1/1,000$  to  $< 1/100$ ); rare ( $\geq 1/10,000$  to  $< 1/1,000$ ); very rare ( $< 1/10,000$ ), including isolated reports.

**Table 4 Adverse reactions reported in at least one pivotal trial in at least 5% of patients and at a higher rate in the Afinitor arm than in the placebo arm**

System Organ Class	Very common	Common
<b>Infections and infestations</b>	infections <sup>1</sup>	
<b>Metabolism and nutrition disorders</b>	decreased appetite <sup>2</sup>	diabetes mellitus
<b>Vascular disorders</b>		hypertension
<b>Nervous system disorders</b>	dysgeusia, headache	
<b>Respiratory, thoracic and mediastinal disorders</b>	cough, pneumonitis <sup>3</sup> epistaxis, dyspnoea

<sup>a</sup> Includes stomatitis, aphthous stomatitis, gingival pain/swelling/ulceration, glossitis, glossodynia, lip ulceration, mouth ulceration, tongue ulceration, and mucosal inflammation.

<sup>b</sup> Includes diarrhea, enteritis, enterocolitis, colitis, defecation urgency, and steatorrhea.

<sup>c</sup> Includes pneumonitis, interstitial lung disease, pulmonary fibrosis and restrictive pulmonary disease.

Other notable adverse reactions occurring in at least one phase III trial more frequently with Afinitor than with placebo, but with an incidence of <5% are listed below. All terms included are based on the highest percentage reported in a pivotal trial.

#### *Blood and lymphatic system disorders*

Uncommon: Pure red cell aplasia (<1%)

#### *Metabolism and nutrition disorders*

Common: dehydration (2.5%), exacerbation of pre-existing diabetes mellitus (1.1%)

Uncommon: new onset of diabetes mellitus (<1%)

#### *Psychiatric disorders*

Common: insomnia (3.3%)

#### *Nervous system disorders*

Uncommon: ageusia (<1%)

#### *Vascular disorders*

Common: haemorrhage (4.7%, at various locations)

Uncommon: deep vein thrombosis (<1%)

#### *Cardiac disorders*

Uncommon: congestive cardiac failure (<1%)

*Respiratory, thoracic and mediastinal disorders*

Common: pulmonary embolism (1.5%), haemoptysis (1.1%)  
Uncommon: acute respiratory distress syndrome (<1%)

*Gastrointestinal disorders*

Common: oral pain (3.7%), abdominal pain (3.6%), dysphagia (2.9%), dyspepsia (2.6%)

*Eye disorders*

Common: eyelid oedema (3.3%), conjunctivitis (1.5%)

*Skin and subcutaneous tissue disorders*

Common: hand and foot syndrome (4.7%), erythema (3.6%), acneiform dermatitis (3.3%), onychoclasia (2.9%), skin exfoliation (1.8%)

*Musculoskeletal and connective tissue disorders*

Common: arthralgia (2.8%)

*Renal and urinary disorders*

Common: proteinuria (2.5%), renal failure (2.3%, including acute renal failure), increased daytime urination (1.8%)

*General disorders and administration site conditions*

Common: chest pain (1.1%).  
Uncommon: impaired wound healing (<1%)

**Key observed laboratory abnormalities were reported in at least one pivotal trial at a higher rate in the Afinitor arm than in the placebo arm.**

In the phase III 1 trials, the majority of observed key laboratory abnormalities were reported with an incidence of  $\geq 10\%$  (listed in decreasing frequency):

Decreased hematology parameters include hemoglobin, lymphocytes, platelets, and neutrophils (or collectively as pancytopenia). Increased clinical chemistry parameters include cholesterol, triglycerides, glucose, aspartate transaminases, creatinine, alanine transaminases, and bilirubin. Decreased clinical chemistry parameters include phosphate and potassium.

Most of observed abnormalities were mild (grade 1) or moderate (grade 2). Grade 4 abnormalities were only observed with an incidence of  $\leq 2.2\%$  and include increases in creatinine (1%), AST, bilirubin, and glucose (each <1%) and reductions in lymphocytes (2.2%), hemoglobin (2%), neutrophils, platelets, and phosphate (each <1%). Decreased potassium, Grade 4, occurred only in patients with advanced pNET primarily of gastrointestinal or lung origin with an incidence of 2%.

Grade 4 abnormalities included reductions in lymphocytes (2.2%), hemoglobin (2%), and potassium (2%), neutrophils, platelets, and phosphate (each <1%) and increases in creatinine (1%), cholesterol, AST, ALT, bilirubin, and glucose (each <1%)

**Table 7 Key laboratory abnormalities reported at a higher rate in the Afinitor arm than in the placebo arm**

### **SEGA**

The data described below reflect exposure to Afinitor (n=28) in a phase II study for the treatment of SEGA. In total, 17 of the 28 patients were exposed to Afinitor for  $\geq 21$  months. Total exposure was 55.2 patient-years. The median age of patients was 11 years (range 3 to 34).

The most common adverse reactions (incidence  $\geq 10\%$  and suspected to be related to treatment by the investigator) were infections, stomatitis, pyrexia, acneiform dermatitis, diarrhoea, acne, cough, hypertriglyceridaemia, and decreased white blood cell count. The only grade 3 adverse reactions were infections (single cases of sinusitis, pneumonia, tooth infection, and viral bronchitis), and single cases of stomatitis and decreased white blood cell count. No grade 4 adverse reactions were reported.

Table 9 summarises the incidence of treatment-emergent adverse reactions reported with an incidence of  $\geq 5\%$ . Adverse reactions are listed according to MedDRA system organ class. Within each system organ class, the adverse reactions are ranked by frequency, with the most frequent reactions first.

CTCAE Version 3.0

<sup>b</sup> Reported as a laboratory abnormality in 43% of patients

<sup>c</sup> Reported as a laboratory abnormality in 54% of patients

Other notable adverse reactions (with an incidence of < 5%) include:

*Psychiatric disorders*

Common: anxiety (3.6%)

*Nervous system disorders*

Common: somnolence (3.6%)

*Vascular disorders*

Common: hypertension (3.6%)

**Attachment 1: Product information for AusPAR Afinitor everolimus Novartis Pharmaceuticals Australia Pty Ltd PM-2011-01215-3-4 Final 26 February 2013. This Product Information was approved at the time this AusPAR was published.**

*Respiratory, thoracic and mediastinal disorders*

Common: Pharyngeal inflammation, increased upper airway secretion, Oropharyngeal or rhinorrhea pain (3.6%)

*Skin and subcutaneous tissue disorders*

Common: dry skin (3.6%), pityriasis rosea (3.6%)

*General disorders and administration site conditions*

Common: fatigue (3.6%), peripheral oedema (3.6%)

*Eye disorders*

Common: ocular hyperaemia (3.6%)

*Investigations*

Single grade 1 reactions are not included.

**Key laboratory abnormalities not reported as adverse drug reactions**

Single cases of grade 3 elevated aspartate transaminase (AST) concentrations and low absolute neutrophil count (ANC) were reported. No grade 4 laboratory abnormalities were noted. Laboratory abnormalities observed in > 1 patient (and listed in decreasing order of frequency) included elevations in AST concentrations (89%), total cholesterol (64%), alanine transaminase (ALT) (43%), glucose (25%), and creatinine (11%), and reductions haemoglobin (39%), glucose (29%), and platelet counts (21%). Most of these laboratory abnormalities were mild (grade 1).

**Adverse Reactions of special interest**

In clinical trials, everolimus has been associated with serious cases of hepatitis B reactivation, including fatal outcome. Reactivation of infections is an expected event during periods of immunosuppression.

In clinical trials and post-marketing spontaneous reports, everolimus has been associated with renal failure events (including fatal ones) and proteinuria. Monitoring of renal function is recommended (see PRECAUTIONS section).

**DOSAGE AND ADMINISTRATION**

Treatment with Afinitor should be initiated by a physician experienced in the use of anticancer therapies.

Afinitor should be administered orally once daily at the same time every day (preferably in the morning), either consistently in a fasting state or consistently after no more than a light fat-free meal (see Pharmacokinetics).

Afinitor tablets should be swallowed whole with a glass of water. The tablets should not be chewed or crushed. For patients unable to swallow tablets, Afinitor tablets should be dispersed completely in a glass of water (containing approximately 30 mL) by gently stirring, immediately prior to drinking. The glass should be rinsed with the same volume of water and the rinse completely swallowed to ensure the entire dose is administered.

If a dose is missed, the patient should take the next dose at the next scheduled time. Patients should not take two doses to make up for the one that they missed.

Treatment should continue as long as clinical benefit is observed or until unacceptable toxicity occurs.

## Adults

### **Dosing in advanced neuroendocrine tumours of pancreatic origin and advanced renal cell carcinoma**

Treatment with Afinitor should be initiated by a physician experienced in the use of anticancer therapies.

The recommended dose of Afinitor is 10 mg to be taken once daily.

Management of severe and/or intolerable suspected adverse reactions may require temporary dose reduction and/or interruption of Afinitor therapy. If dose reduction is required, the suggested dose is 5 mg daily (see Precautions).

#### *Moderate CYP3A4 or PgP inhibitors:*

Use caution when administered in combination with moderate CYP3A4 inhibitors or PgP inhibitors. If patients require co-administration of a moderate CYP3A4 or PgP inhibitor, reduce the dose to 5 mg daily. Further dose reduction to 5 mg every other day or 2.5 mg daily may be required to manage adverse reactions (see Precautions).

#### *Strong CYP3A4 or PgP inducers:*

Avoid the use of concomitant strong CYP3A4 inducers. If patients require co-administration of a strong CYP3A4 inducer, an Afinitor dose increase from 10 mg daily up to 20 mg daily should be considered (based on pharmacokinetic data), using 5 mg increments. This dose of Afinitor is predicted to adjust the AUC to the range observed without inducers. However, there are no clinical data with this dose adjustment in patients receiving strong CYP3A4 inducers. If the strong inducer is discontinued the Afinitor dose should be returned to the dose used prior to initiation of the strong CYP3A4 inducer (see Precautions).

### **Dosing in SEGA associated with TS**

Treatment with Afinitor should be initiated by a physician experienced in the treatment of patients with TS and with access to everolimus therapeutic drug monitoring services. Therapeutic drug monitoring of everolimus blood concentrations is required for patients treated for SEGA (see “Therapeutic Drug Monitoring” in the text below).

Titration may be required to obtain the optimal therapeutic effect. Doses that are tolerated and effective vary between patients. Concomitant antiepileptic therapy may affect the metabolism of everolimus and may contribute to this variance (see Interactions with Other Medicines).

The recommended starting dose of Afinitor for treatment of patients with SEGA is according to Table 10:

**Table 10 Recommended starting dose of Afinitor for treatment of patients with SEGA**

<b>Body Surface Area (BSA)*</b>	<b>Starting daily dose</b>
1.2 m <sup>2</sup>	2.5 mg
1.3 m <sup>2</sup> to 2.1 m <sup>2</sup>	5 mg
2.2 m <sup>2</sup>	7.5 mg

\*BSA =  $\sqrt{(\text{Height(cm)} \times \text{Weight(kg)})/3600}$

Everolimus whole blood trough concentrations should be assessed approximately 2 weeks after commencing treatment. Dosing should be titrated to attain trough concentrations of 5 to 10 ng/mL. If concentrations are below 5 ng/mL, the daily dose may be increased by 2.5 mg every 2 weeks, subject to tolerability (see Pharmacokinetics).

SEGA volume should be evaluated approximately 3 months after commencing Afinitor therapy, with subsequent dose adjustments taking into consideration changes in SEGA volume, corresponding trough concentration, and tolerability (see Pharmacokinetics).

Responses have been observed at trough concentrations as low as 2 ng/mL; as such, once acceptable efficacy has been achieved, additional dose increase may not be necessary. Management of severe or intolerable adverse reactions may require temporary dose reduction and/or interruption of therapy (see Precautions). If dose reduction is required for patients receiving 2.5 mg daily, alternate day dosing should be considered.

**Moderate CYP3A4 or PgP inhibitors:** Use caution when administered in combination with moderate CYP3A4 inhibitors or PgP inhibitors. If patients require co-administration of a moderate CYP3A4 or PgP inhibitor, reduce the daily dose by approximately 50%. Further dose reduction may be required to manage adverse reactions (see Precautions). Everolimus trough concentrations should be assessed approximately 2 weeks after the addition of a moderate CYP3A4 or PgP inhibitor. If the moderate inhibitor is discontinued the Afinitor dose should be returned to the dose used prior to initiation of the moderate CYP3A4 or PgP inhibitor and the everolimus trough concentration should be re-assessed approximately 2 weeks later (see Precautions).

**Strong CYP3A4 inducers:** Avoid the use of concomitant strong CYP3A4 inducers. Patients receiving concomitant strong CYP3A4 inducers (e.g., enzyme inducing antiepileptic drug) may require an increased Afinitor dose to attain trough concentrations of 5 to 10 ng/mL. If concentrations are below 5 ng/mL, the daily dose may be increased by 2.5 mg every 2 weeks, checking the trough level and assessing tolerability before increasing the dose. If the strong inducer is discontinued the Afinitor dose should be returned to the dose used prior to initiation of the strong CYP3A4 inducer and the everolimus trough concentrations should be assessed approximately 2 weeks later (see Precautions).

## Therapeutic drug monitoring for patients treated for SEGA

Therapeutic drug monitoring of everolimus blood concentrations is required for patients treated for SEGA using a validated bioanalytical LC/MS method. Trough concentrations should be assessed approximately 2 weeks after the initial dose, after any change in dose, or after an initiation or change in co-administration of CYP3A4 inducers or inhibitors (see Precautions). Dosing should be titrated with the objective of attaining everolimus trough concentrations of 5 to 10 ng/mL, subject to tolerability (see Pharmacokinetics).

There is limited safety experience with patients having trough concentrations > 10 ng/mL. If concentrations are between 10 to 15 ng/mL, and the patient has demonstrated adequate tolerability and tumour response, no dose reductions are needed. The dose of Afinitor should be reduced if trough concentrations > 15 ng/mL are observed.

## Paediatric population

- Advanced neuroendocrine tumours of pancreatic origin and renal cell carcinoma: Afinitor is not recommended for use in paediatric cancer patients.
- SEGA: Dosing recommendations for paediatric patients with SEGA are consistent with those for the adult SEGA population. Afinitor has not been studied in paediatric SEGA patients < 3 years of age and is currently not recommended for use in this age group.

## Elderly patients (≥ 65 years)

No dosage adjustment is required (see Pharmacokinetics).

## Patients with renal impairment

No dosage adjustment is required (see Pharmacokinetics).

## Patients with hepatic impairment

### Advanced neuroendocrine tumours of pancreatic origin and renal cell carcinoma:

- the dose should be reduced to 5 mg daily in patients with moderate hepatic impairment (Child-Pugh class B).
- For patients with severe hepatic impairment (Child-Pugh class C): Everolimus has not been evaluated in patients with severe hepatic impairment and is not recommended for use in this patient population (see Precautions and Pharmacokinetics).

### SEGA:

- the dose should be reduced by approximately 50% and titrate to trough concentrations of 5 to 15 ng/mL
- For patients with severe hepatic impairment (Child-Pugh class C): Everolimus has not been evaluated in patients with severe hepatic impairment and is not recommended for use in this patient population (see Precautions and Pharmacokinetics).

## **OVERDOSAGE**

In animal studies, everolimus showed a low acute toxic potential. No lethality or severe toxicity was observed in either mice or rats given single oral doses of 2000 mg/kg (limit test).

Reported experience with overdose in humans is very limited. Single doses of up to 70 mg have been given with acceptable acute tolerability.

General supportive measures should be initiated in all cases of overdose.

Contact the Poisons Information Centre on 13 11 26 for advice on management.

## **PRESENTATION AND STORAGE CONDITIONS**

2.5 mg tablet: White to slightly yellowish, elongated tablet with a bevelled edge and no score engraved with "LCL" on one side and "NVR" on the other. Packs of 30, 50, 60 and 100, 120 tablets.

5 mg tablet: White to slightly yellowish, elongated tablet with a bevelled edge and no score engraved with "5" on one side and "NVR" on the other. Packs of 30, 50, 60 and 100, 120 tablets.

10 mg tablet: White to slightly yellowish, elongated tablet with a bevelled edge and no score engraved with "UHE" on one side and "NVR" on the other. Packs of 30, 50, 60, 100 and 120 tablets.

Not all pack sizes may be marketed.

Store below 30°C in the original packaging. Protect from light and moisture.

## **NAME AND ADDRESS OF THE SPONSOR**

Novartis Pharmaceuticals Australia Pty Limited  
(ABN No: 18 004 244 160)  
54 Waterloo Road  
NORTH RYDE NSW 2113

## **POISON SCHEDULE OF THE MEDICINE**

Prescription Only Medicine (Schedule 4).

## **DATE OF FIRST INCLUSION IN THE AUSTRALIAN REGISTER OF THERAPEUTIC GOODS (THE ARTG)**

6 August 2009
